

Decentralized Autonomous Cross Chain Bonds

Introduction

The Gilt protocol has been created to establish a new type of financial vehicle that leverages the ERC721 mechanism to implement a bonding protocol that provides the foundation for more sophisticated DeFi.

Today cross chain DeFi is typified by the transfer of raw capital across blockchains exposing participants to numerous protocol exploit risks which further force the industry back towards more centralised methods of risk management. In short what is done today is the equivalent of moving 1 Trillion dollars in an armoured van every time we want to do a cross chain transaction. In addition to that not all tokens are supported across chains.

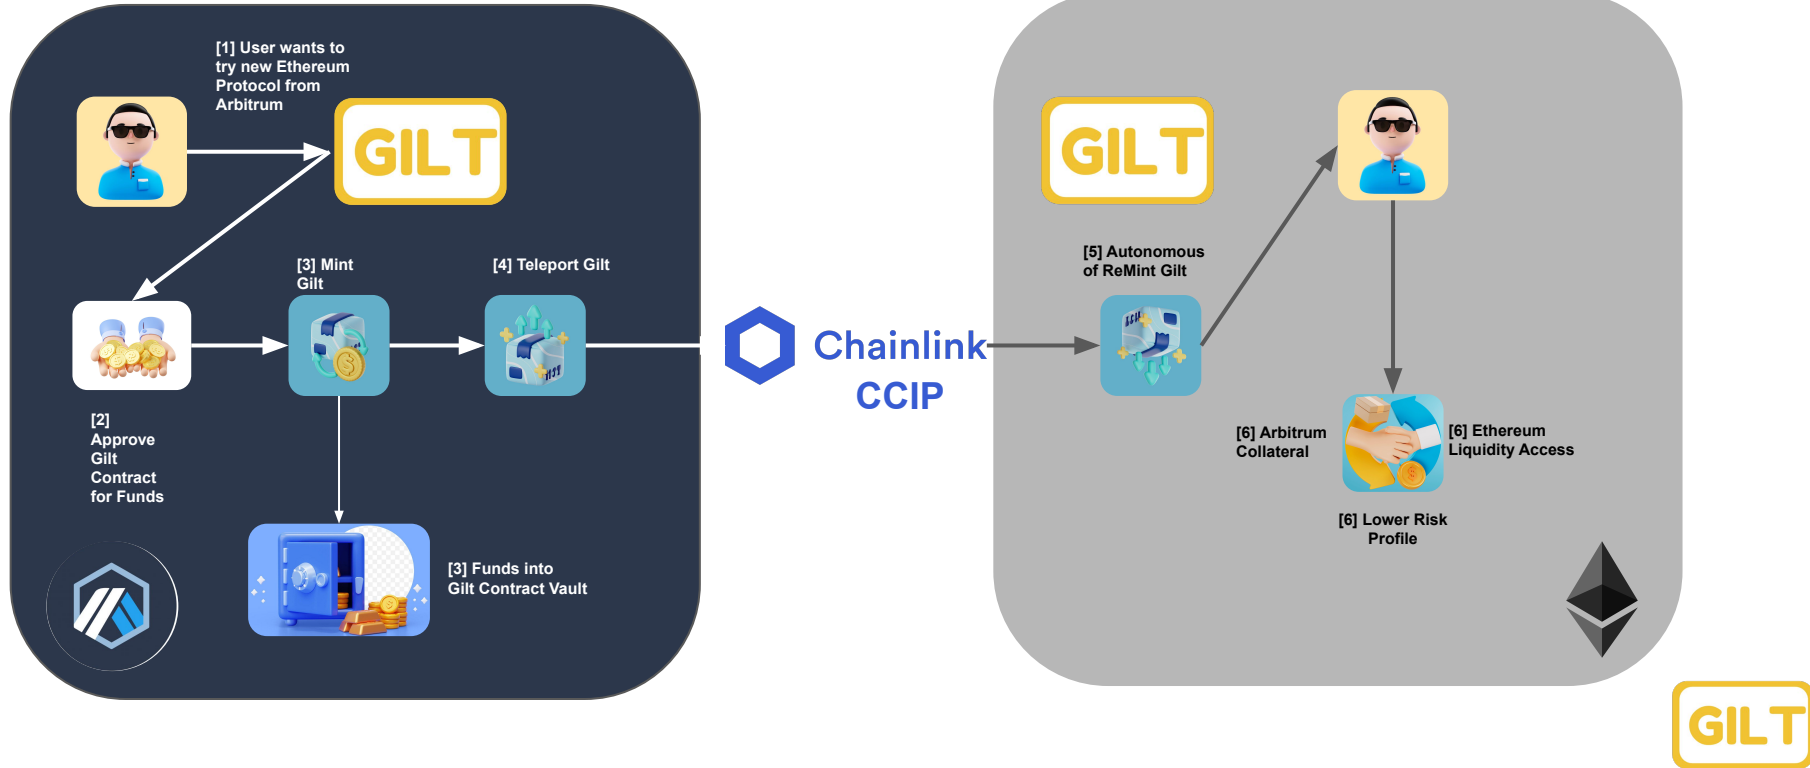

The solution to these challenges is the Gilt Protocol.
